ILNP: A whirlwind tour

Saleem Bhatti

School of Computer Science

University of St Andrews
Outline

1. What?
   • Basic information about ILNP.
2. Why?
   • The rationale for ILNP.
3. How?
   • Basic operation of ILNP.
4. When?
   • ILNP development.
What is ILNP?

• Identifier Locator Network Protocol:

• ILNP enhances Internet Protocol functionality through the use of crisp **naming**.

• March 2010: IRTF RRG Chairs recommend ILNP for development within the IETF:
  [http://www.ietf.org/mail-archive/web/rrg/current/msg06356.html](http://www.ietf.org/mail-archive/web/rrg/current/msg06356.html)

• People:
  • Ran Atkinson (Cheltenham Research, US)
  • Saleem Bhatti (University of St Andrews, UK)
This is a work in progress:

- http://ilnp.cs.st-andrews.ac.uk/

Focus on network and transport layers (for now)

This talk – ILNPv6 as a parallel/concurrent system on the existing Internet infrastructure:

- We take a bottom-up engineering approach.
- Initial idea based on Mike O'Dell's 8+8/GSE (1996/7)
  - Many enhancements compared to 8+8/GSE
  - Initial “IPv6 8+8” idea dates from emails posted by Bob Smart (02 Jun 1994) and Dave Clark (11 Jan 1995):
    http://www.ietf.org/mail-archive/web/rrg/current/msg02455.html
Outline

1. What?
   - Basic information about ILNP.

2. Why?
   - The rationale for ILNP.

3. How?
   - Basic operation of ILNP.

4. When?
   - ILNP development.
(New) Requirements

• We wish to try and support a *harmonised solution to many network functions*:
  
  • Multi-homing (host and site).
  
  • Mobility (host and network).
  
  • Multi-path capable transport protocols.
  
  • Localised addressing (NAT).
  
  • Traffic engineering capability.
  
  • Packet-level, end-to-end security.

• Currently, solutions for these functions remain disparate and do not function well together.
Engineering issues for ILNPv6

We wish to have an incrementally deployable solution that is also backwards compatible:

1. Core network devices and protocols should not need to change, e.g. routers, switches of today can be used without modification.

2. Reuse the existing core protocol deployment as much as possible, e.g. make use of existing IPv6.

3. Try to limit the impact on current applications (but we have to accept some applications might break).

4. The end system stack will need to change, but changes should run in parallel with current stack.
Names

• My definition of a “name”:

A set of bits used to label an object. The semantics of the name are defined within the context of use of the object it names.

• Examples:
  
  • protocol name – ‘http’
  • port number – ‘80’
  • fully qualified domain name (FQDN), e.g. ‘marston.cs.st-andrews.ac.uk’
  • IP address - ‘138.251.195.61’
Application layer protocols

• URLs:
  https://marston.cs.st-andrews.ac.uk/

• Can also use an IP address:
  https://138.251.195.61/

• Notice, the use of either a DNS name or an IP address – FQDN and IP address used as synonyms.

• IP address is overloaded:
  • used in application protocols as a session identifier
Transport protocols

• TCP uses a tuple to **identify** a TCP connection:
  • local **IP address**
  • local port number
  • remote **IP address**
  • remote port number

• TCP state (and the pseudo-header checksum) is bound to **all** the bits in the local and remote IP address.

• **IP address used as an Identifier.**
Network layer

• IP address bits are used in **routing**:
  
  • IP address (network) prefix, e.g.
    138.251.195.61/24
    means that 138.251.61 (the network prefix) is used for routing at the IP layer

• The host part of the address may be further used for sub-netting at the site:
  
  • IP sub-netting on host bits, e.g.
    138.251.195.61/25
    means 1 bit of the host part of the address is used

• **IP Address used as a Locator.**
Interface identifier
IAB Naming and Addressing Workshop 18-19 October 2006
RFC4984, p6

... workshop participants concluded that the so-called "locator/identifier overload" of the IP address semantics is one of the causes of the routing scalability problem as we see today. Thus, a "split" seems necessary to scale the routing system, although how to actually architect and implement such a split was not explored in detail.
RFC2101 (Feb 1997)

IPv4 Address Behaviour Today
RFC2101 pp 3-4

Identifiers should be assigned at birth, never change, and never be re-used. Locators should describe the host's position in the network's topology, and should change whenever the topology changes. Unfortunately neither of the these ideals are met by IPv4 addresses.
IEN 1 (29 July 1977)

• Section 3 ADDRESSING (pp 6-12):
  • Discusses physical vs. logical addressing

• Section 3.2 Special Topologies (pp 7-8):
  • Specifically discusses “Changes in Topology” (mobility) and “Multiply-Connected Hosts” (multi-homing)
  • Flags problems with use of IP addresses (as today).

• Lots of wisdom:
  • IENs 19, 23, 31, 46
Layers are entangled

<table>
<thead>
<tr>
<th>Protocol Layer</th>

<td>Network</td>
<td>IP address</td>
<td>Locator</td>
</tr>
<tr>
<td>(Interface)</td>
<td>IP address</td>
<td>(dynamic mapping)</td>
</tr>
</tbody>
</table>

**Entanglement 😞**  **Separation 😊**

FQDN = fully qualified domain name
ILNPv6

• Can be seen as a set of 'extensions' to IPv6:
  • Uses same packet format as IPv6 in network core.
  • IPv6 core routers do not need to change.
  • Incrementally deployable on IPv6 core.
  • Backwards compatible with IPv6.

• Split 128-bit IPv6 address:
  • 64-bit Locator (L) - network name.
  • 64-bit Identifier (I) - node name.

• Could also be retro-fitted to IPv4 (but messy).
IPv6 addresses and ILNPv6

IPv6 (as in RFC3587):

+---+---------------------+-----------+----------------------------+
|001|global routing prefix| subnet ID | Interface Identifier |
+---+---------------------+-----------+----------------------------+

same syntax, different semantics

ILNPv6:

+---+---------------------+-----------+----------------------------+
| | Locator             | Node Identifier |
+---+---------------------+-----------+----------------------------+

same syntax and semantics as IPv6 routing (address) prefix
these bits only examined and acted upon by end systems

so IPv6 core routers work as today

</tr>
</tbody>
</table>
Locators and Identifiers [1]

- **Locator, L:**
  - Topologically significant.
  - Names a (sub)network (as today's network prefix).
  - Used only for routing and forwarding in the core.

- **Identifier, I:**
  - Is not topologically significant.
  - Names a logical/virtual/physical node, does not name an interface (value ala RFC4291 Sec 2.5.1).

- Upper layer protocols bind only to Identifier.
Locators and Identifiers [2]

• Locator, L:
  • **Can change** value during the lifetime of a transport session (mobility, site-controlled traffic engineering).
  • Multiple Locators can be used simultaneously (multi-homing, multi-path transport protocols).

• Identifier, I:
  • **Remains constant** during the lifetime of a transport session (localised addressing, IPsec.).
  • Multiple Identifiers can be used simultaneously by a node, but not for the same session.
Mapping FQDNs to I/L values

• DNS is used as today:
  • FQDN is used to map to I/L values instead of AAAA

• Need new DNS Resource Records, e.g.:
  • I64 – 64-bit Identifier value, EUI-64 syntax
  • L64 – 64-bit Locator value
  • LP – Locator Pointer (like CNAME for L64)

• DNS lookup will return:
  • 1 or more I64 records, 1 or more L64 records
  • For multiple I64 and L64 RRs, use preference bits
DNS enhancements required

<table>

<td>LP</td>
<td>Forward pointer from FQDN to an L record</td>
</tr>
</tbody>
</table>

FQDN = fully qualified domain name
Examples of ILNP usage

SBR = site border router
NAT in IPv4 and IPv6

NAT allows address reuse for a site:
- single address shared amongst many hosts (use of port numbers)
- End-to-end view is lost, as identity namespace has a discontinuity at the SBR
NAT in ILNPv6

- NAT is now a feature not a hack:
  - L is not part of the end system transport session state.
  - $L_L$ value ala RFC4193
  - end-to-end view
- SBRs perform **Locator rewriting** without affecting end-to-end state.
Mobile networks in ILNP [1]

- Use NAT to ‘hide’ the movement to internal nodes.
- SBR changes Locator value as the mobile network moves:
  - Sends Locator Update (LU) messages to correspondents.
  - Updates DNS.

Mobile networks in ILNPv6 [2]

- Network layer soft-hand-off possible in ILNP.
- Requires at least 2 radio channels (or 2 radio interfaces).
- SBRs can handle Locator rewriting and forwarding as required.
Mobile hosts in ILNPv6

- Mobility/multi-homing duality.
- An individual mobile host (MH) picks up a new Locator value as it moves into a new network.
- MH sends Locator Update (LU) messages to correspondents for existing sessions.
- MH updates DNS with new Locator value.
- If cells overlap, MH can use multiple Locator values simultaneously for soft hand-off.
Multi-homing in ILNPv6 [1]

- For IP today, Provider Independent (PI) prefixes are popular:
  - Prefix $\equiv$ identity.
  - No renumbering.

- Multi-homing prefixes can lead to bloat in the RIB of the DFZ:
  - Non-aggregateable prefixes.

Additional RIB entries per site:

$N_L \cdot N_P$

$N_L$ = number of links
$N_P$ = number of prefixes
Multi-homing in ILNPv6 [2]

- ILNP, Locator taken from the allocated prefixes of ISP:
  - Identity not related to Locator.
  - Renumbering through operation of IPv6.
- No extra prefixes required:
  - All Locator values visible via DNS.
VM migration

Past relevant work

- Our work is based on the following key ideas:
  - IEN1 (1977): separate names for layer 3 & layer 4
  - Bob Smart (c. 1994): email to public SIPP list proposing an 8+8 split for the IPv6 address.
  - Dave Clark (c.1995): email to public IRTF list proposing 8+8 plus ideas on enabling functionality.
  - Mike O'Dell (c.1997): IETF drafts on GSE and 8+8.
  - IRTF NameSpace RG (NSRG)
- We have enhanced and extended those early ideas in order to address a comprehensive set of functionality through naming.
Current relevant work

- Host Identity Protocol (HIP) – host-based:
  - IRTF and IETF, RFC4423
  - Research grade implementation available.
  - Uses public-key (non public-key option?)

- SHIM6 – host-based (IETF drafts):
  - Research grade implementation available.

- LISP – network based (IETF drafts):
  - Use of tunnels and additional state/signalling.

- MEXT – host and network mobility (IETF drafts):
  - Aims to combine MIPv6, NEMO and IKEv2.
Other related work on architecture

- NIMROD
- IP Next Layer (IPNL)
- TurfNet
- Internet Indirection Infrastructure (I³)
- Others ... (see the list of references in the papers on ILNP WWW site)
Outline

1. What?
   • Basic information about ILNP.

2. Why?
   • The rationale for ILNP.

3. How?
   • Basic operation of ILNP.

4. When?
   • ILNP development.
Development options

• Simulation:
  • Good control, high-scalability, reproducibility of experiments etc.

• Emulation:
  • e.g. use of an overlay network is feasible (Masters student project, 2009), with constraints.
  • OneLab, PlanetLab (control + mgmt + monitoring?)

• Test-bed – implementation in OS stack:
  • prototype Linux (~Q3 2011?)
  • prototype FreeBSD (~Q4 2011?)
No free lunch

• DNS support – not new, but explicit in ILNPv6:
  • New RRs + **zero TTL for some DNS records**.
  • Secure DNS Dynamic Update for Locator changes.
• Renumbering + address management at sites.
• No globally routeable interface name, which may impact some applications such as SNMP.
• Some legacy applications may break, e.g. FTP.
• Interworking scenarios (IPv6, IPv4).
Thank You!

• More information on ILNP:

• Contact information:
  • Saleem Bhatti <saleem@cs.st-andrews.ac.uk>
Supplementary slides
The clear, highest-priority takeaway from the workshop is the need to devise a scalable routing and addressing system, one that is scalable in the face of multihoming, and that facilitates a wide spectrum of traffic engineering (TE) requirements.
Problems today

• The growth of the DFZ RIB:
  • currently at ~300,000+ entries and growing

• Multi-homing:
  • increasingly popular for customers

• Traffic Engineering:
  • a useful tool for providers and customers

• Provider Independent Addressing:
  • address is a form of identity; re-numbering is hard
User programs – Java API

• TCP Client:
  
  ```java
  Socket skt = new Socket("srv.blob.com", 1234);
  ```

• Can also use an IP address:
  
  ```java
  Socket skt = new Socket("10.12.14.16", 1234);
  ```

• Notice, the use of **either** a DNS name or an IP address – FQDN and IP address used as synonyms.

• **IP address is overloaded**:
  
  • may be used in application code in place of FQDN
In general, user applications should use names rather than addresses.
Locators and Identifiers [3]

- **Locator, L:**
  - Network prefix, from normal configuration or using discovery protocol (e.g. IPv6 Router Advertisement).

- **Identifier, I:**
  - Default value: a node uses bits from a local interface to form an EUI-64 value, which is used as an Identifier for that node.
  - Other interesting possibilities ... (work in progress).
  - Strictly, needs to be unique within scope of a given Locator value: global uniqueness is good, however.
Comparison with LISP [1]

• **LISP**: customer focused, practically-directed engineering solution, with a goal of minimal cost to end sites, employing network upgrades that would be invisible to the end users, and reduce the burden of routing state on "core network". Objective is to provide a product-based solution.

• **ILNPv6**: research vehicle to explore the current use of addressing and examine fundamental architectural issues of how naming can be used to enable new functionality. Objective is to give a proof-of-concept implementation in order to demonstrate that ILNP could be made to work as described.
## Comparison with LISP [2]

IHL: Internet Header Length   OT: Option Type   OL: Option Length
Traffic Engineering in ILNP

- SBR(s) can use today's policy-based approaches for filtering and forwarding with **Locator rewriting**.
- Incoming packets can also be redirected across SBRs.

Policy mechanisms to decide on which links packets are forwarded.
IPsec

- IPsec currently uses the whole of the IP address for binding a Security Association (SA).

- In ILNP, the SA binds only to the Identifier, I:
  - I remains constant throughout the session.
  - L value can change (for whatever reason) while the session is in progress.
  - As long as I does not change, end-to-end session state is maintained.
No free lunch [1]

◆ To support mobility and dynamic multi-homing:
  - TTL for DNS records needs to be set as low as possible, ideally to zero.
  - TTL for DNS records for fixed sites can remain as used today.

◆ To support multi-homing and TE:
  - L64 records could benefit from the use of preference bits to indicate preferred Locator usage.
No free lunch [2]

- No globally routeable interface name, which may impact some applications such as SNMP.
- Some legacy applications may break, e.g. FTP.
- DNS reliance in ILNPv6:
  - Not new, but made explicit in ILNPv6.
  - No new security issues created.
  - Can use DNS Security and Dynamic DNS Update, which is already being worked on within the IETF, and already implemented in DNS servers.
Practical issues – initial thoughts

- Portability of applications?
  - What are the range of problems that might exist for porting applications to ILNPv6?
- Optional, enhanced networking API?
  - Use of names, I:L not seen.
  - Exploit ILNP, e.g. signal for change in L.
- DNS usage impact?
  - How might DNS be affected in real use?
- Adoption in end-system stacks?
ILNPv6 in-house testbed

- Use of existing services:
  - e.g. use of deployed DNS and IPv6 routing.
- Exploit VMs when possible.
- Off-the-shelf equipment:
  - easy of use
  - costs
- Open source:
  - leverage existing kernel code
  - make available to community
Useful features of a testbed [1]

• Kernel code in practical settings – working on low-level protocols is disruptive:
  • things will break!

• Separation of management-, control- and data-(user-) plane functions, logically and physically:
  • out-of-band management and control for nodes.
  • separate control of routing links and routing configuration.
  • data plane connectivity (e.g. via VLANs)
Useful features of a testbed [2]

• Control of experimental nodes:
  • console access for boot messages and control.
  • administrator level access.
  • power control for remote power cycling.

• Support services:
  • Naming (DNS) configuration and control.
  • Network monitoring for troubleshooting and fine-grained operation- and performance-analysis.

• Security: lots of issues ...
Extending testbed to larger scales

• How can we achieve the same level of control and configuration at larger scales?

• Do we need to change the way we undertake low-level protocol development in order to use larger-scale testbeds?

• Are new approaches, such as virtualisation, applicable to such large-scale scenarios with such low-level protocol development?

• Is it possible to conduct such development on distributed, large-scale testbeds?
